

The context of an ATM system

Equipment procurement process

Data-processing models Data flow diagrams (DFDs) may be used to model the system's data processing. These show the processing steps as data flows through a system. DFDs are an intrinsic part of many analysis methods.

• Simple and intuitive notation that customers can understand.

Architectural models

- Used to document an architectural design.
- Static structural model that shows the major system components.
- Dynamic process model that shows the process structure of the system.
- Interface model that defines sub-system interfaces.
- Relationships model such as a data-flow model that shows sub-system relationships.
- Distribution model that shows how sub-systems are distributed across computers.

The repository model

- Sub-systems must exchange data. This may be done in two ways:
 - Shared data is held in a central database or repository and may be accessed by all subsystems;
 - Each sub-system maintains its own database and passes data explicitly to other sub-systems.
- When large amounts of data are to be shared, the repository model of sharing is most commonly used.

Slide 28

CASE toolset architecture

Repository model characteristics

Advantages

- Efficient way to share large amounts of data;
- Sub-systems need not be concerned with how data is produced Centralised management e.g. backup, security, etc.
- Sharing model is published as the repository schema.

Disadvantages

- Sub-systems must agree on a repository data model. Inevitably a compromise;
- Data evolution is difficult and expensive;
- No scope for specific management policies;
- Difficult to distribute efficiently.

Software Engineering, 7th edition. Chapter 8

Client-server model
Distributed system model which shows how data and processing is distributed across a range of components.
Set of stand-alone servers which provide specific services such as printing, data management, etc.
Set of clients which call on these services.
Network which allows clients to access servers.

Abstract machine (layered) model

- Used to model the interfacing of sub-systems.
- Organises the system into a set of layers (or abstract machines) each of which provide a set of services.
- Supports the incremental development of subsystems in different layers. When a layer interface changes, only the adjacent layer is affected.
- However, often artificial to structure systems in this way.

Invoice processing system

Object model advantages

- Objects are loosely coupled so their implementation can be modified without affecting other objects.
- The objects may reflect real-world entities.
- OO implementation languages are widely used.
- However, object interface changes may cause problems and complex entities may be hard to represent as objects.

Function-oriented pipelining

- Functional transformations process their inputs to produce outputs.
- May be referred to as a pipe and filter model (as in UNIX shell).
- Variants of this approach are very common. When transformations are sequential, this is a batch sequential model which is extensively used in data processing systems.

Software Engineering, 7th edition. Chapter 8

Slide 38

• Not really suitable for interactive systems.

Interrupt-driven control

Architecture attributes

- Performance •
- Localise operations to minimise sub-system communication •
- Security Use a layered architecture with critical assets in inner layers .
- Safety
- Isolate safety-critical components
- Availability

 Include redundant components in the architecture
- Maintainability .
 - Use fine-grain, self-contained components .
